Introduction

Impurity Nuclear Physics: since a Λ -particle does not suffer from Pauli blocking, it can locate at the center of a nucleus; then the Λ attracts surrounding nucleons and makes the nucleus shrink. For the E2 electromagnetic transitions the transition probability $B(E2)$ is very sensitive to size contraction as it is approximately proportional to fourth power of the nuclear size

Medium Effects: by the same reason a Λ -particle can be a probe to investigate possible modifications of baryon properties in nuclear matter. For example, the measurement of $B(M1)$ in a spin-flip M1 transition provides information on the magnetic moment of Λ in a nucleus, which may be changed if a baryon is “swelling” in nuclear matter

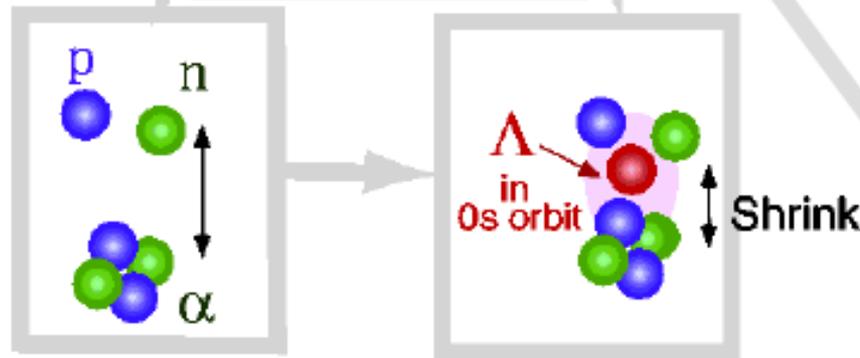

$B(E2)$ and $B(M1)$
can be derived from excited states lifetimes

Results on ${}^7_{\Lambda}\text{Li}$

Predicted by Motoba et al.,
Prog.Theor.Phys.
70 (1983) 189.

shrinking effect

$B(E2)$ [$e^2 \text{fm}^4$]

$10.9 \pm 0.9 \longrightarrow 3.6 \pm 0.5 \pm 0.5$
 0.4

$\Rightarrow 19 \pm 4\%$ shrinkage by Λ

Tanida et al., PRL 86(2001) 1982

spin-spin interaction

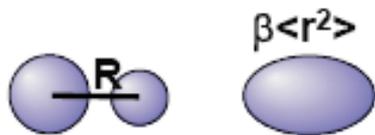

$\Delta = 0.50 \text{ MeV}$

N-LS interaction

$S_N \sim -0.4 \text{ MeV}$

PRL 84 (2000) 5963

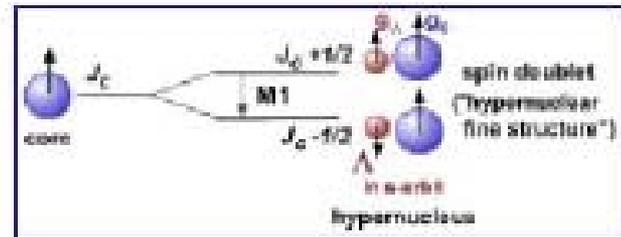

Depicted from Tamura 2004

$B(E2) \cdot |\langle f | e r^2 Y_2 | i \rangle|^2$
 $\cdot R^4$ or $(\beta \langle r^2 \rangle)^2$

Medium effect

If the **mass** or the **size** of a hyperon is modified in a nucleus, its **magnetic moment** may be changed

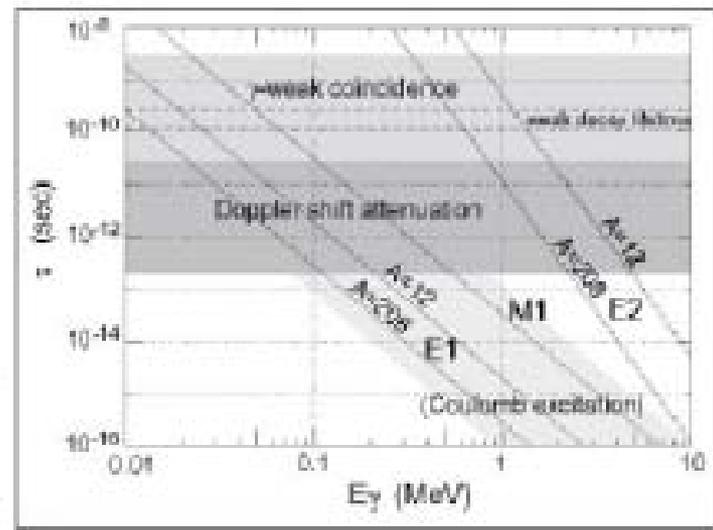

$$B(M1) \propto \left| \langle \phi_{lo} | \mu^z | \phi_{up} \rangle \right|^2 = \left| \langle \phi_{lo} | g_N J_N^z + g_\Lambda J_\Lambda^z | \phi_{up} \rangle \right|^2$$

$$\propto (g_N - g_\Lambda)^2$$

$B(M1)$ can be derived from **excited states lifetimes**

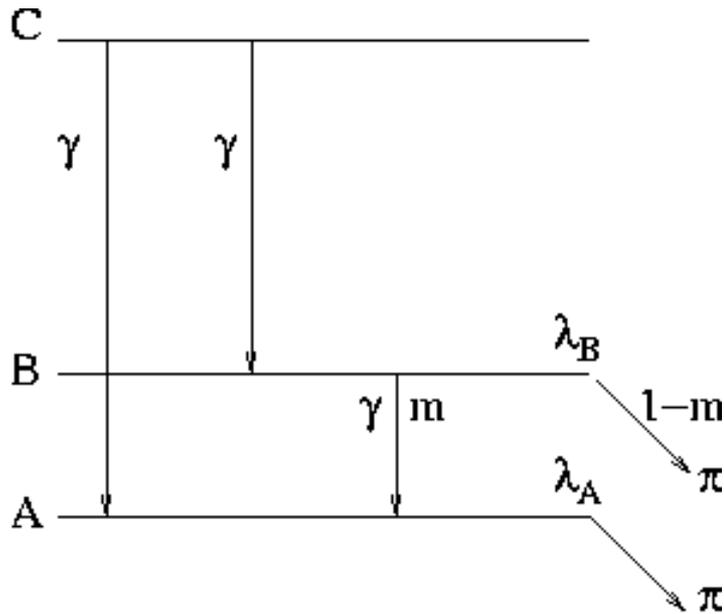

- ❖ **Doppler-shift attenuation method**
- ❖ **γ -weak coincidence method**

Depicted from Bressani 2005

Tagged-Weak π -Method

$$P^{B \rightarrow weak}(t) = (1 - m)\lambda_B (\lambda_B^{\pi^-} / \lambda_B) N_B e^{-\lambda_B t}$$

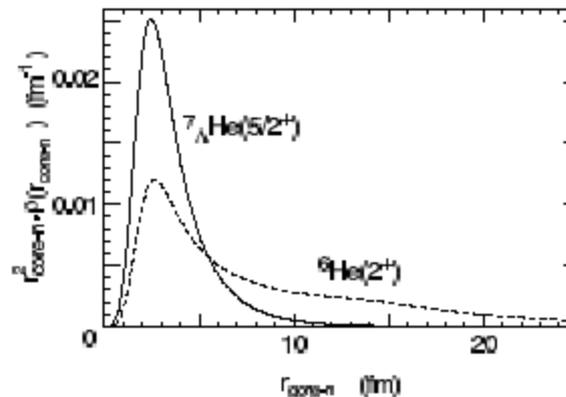

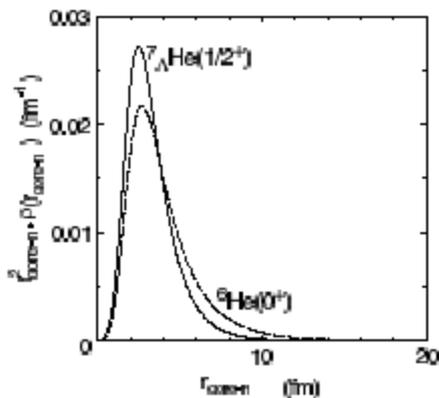

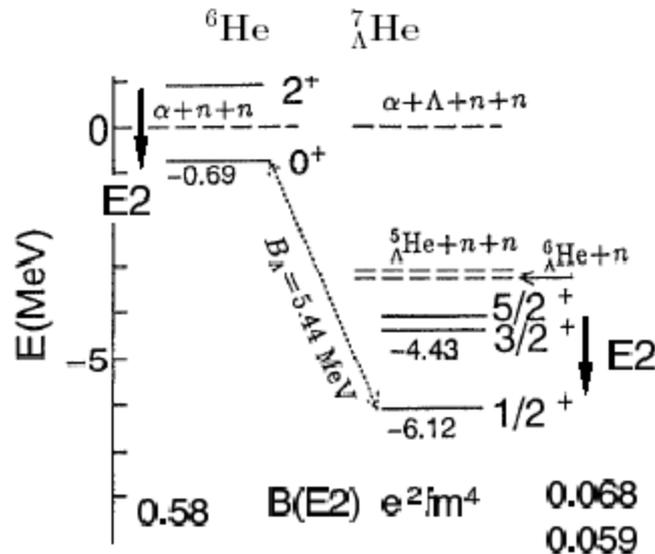

$$P^{A \rightarrow weak}(t) = (P^{B \rightarrow A}(t) + \lambda_A N_A e^{-\lambda_A t}) (\lambda_A^{\pi^-} / \lambda_A)$$

$$P^{B \rightarrow A}(t) = \frac{\lambda_A \lambda_B}{\lambda_A - \lambda_B} m N_B (e^{-\lambda_A t} - e^{-\lambda_B t})$$

By measuring both of $P^{B \rightarrow weak}(t)$ and $P^{A \rightarrow weak}(t)$ and fitting them together to the equations above, λ_A , λ_B and m can be determined, assuming $\lambda_W^A = \lambda_W^B$

$$\lambda_A = \lambda_W^A, \quad \lambda_B = \lambda_W^B + \lambda_\gamma^{B \rightarrow A} \quad \text{and} \quad m = \frac{\lambda_\gamma^{B \rightarrow A}}{\lambda_\gamma^{B \rightarrow A} + \lambda_W^B}$$

Example of ${}^7_{\Lambda}\text{He}$

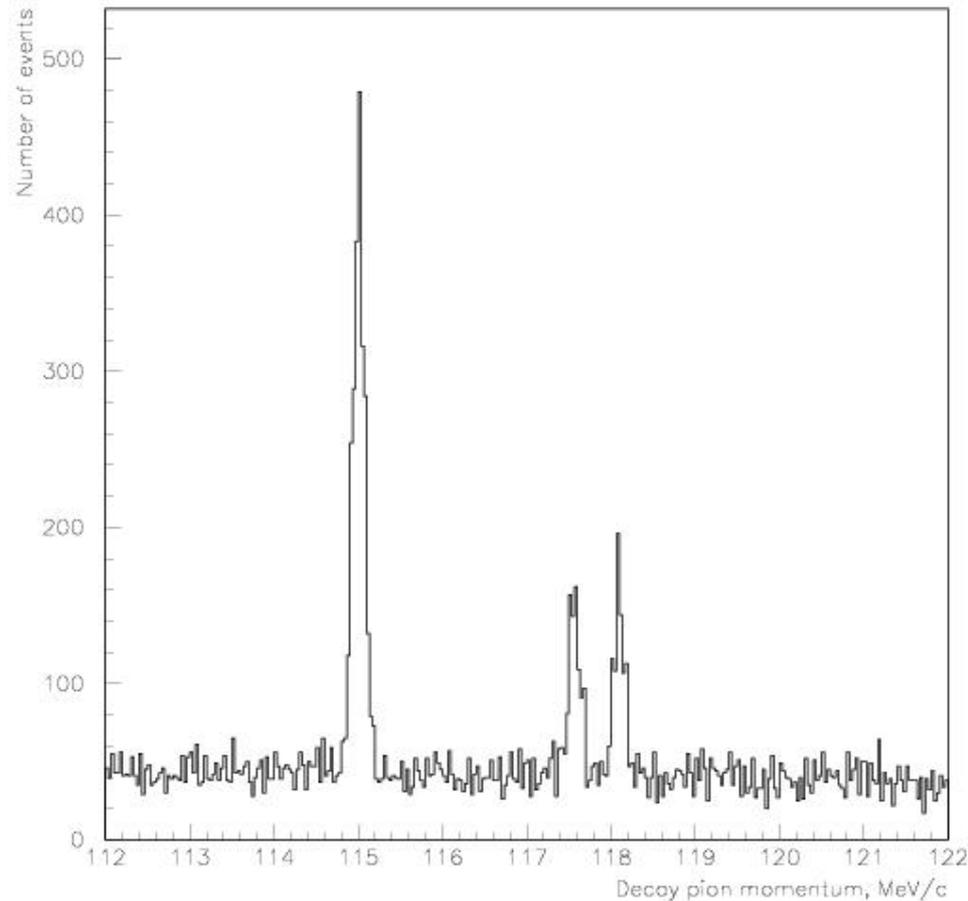

Expected level scheme of ${}^7_{\Lambda}\text{He}$, $B(E2)$, and density distribution of valence neutrons, Hiyama et al., 1996.

${}^7_{\Lambda}\text{He}$

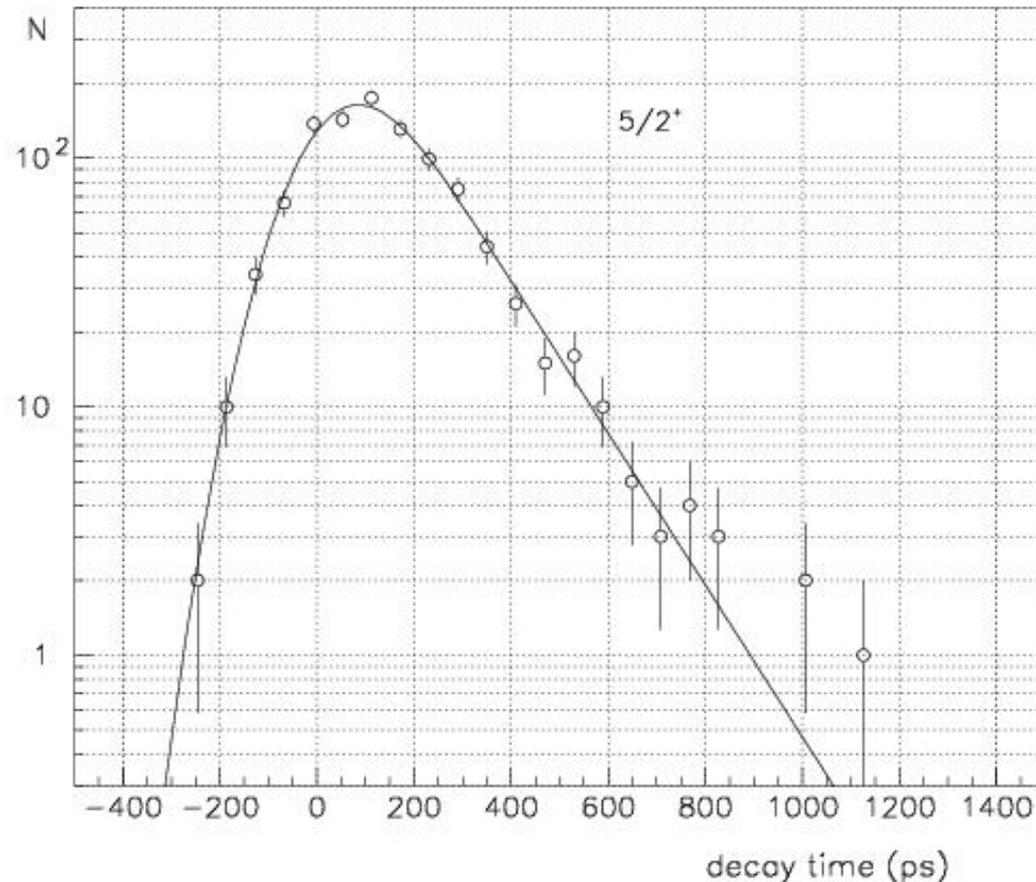

- The first excited state of ${}^6\text{He}$ $2+$ is observed as an unbound
- When we add a Λ to ${}^6\text{He}$, the neutron skin in the ground state is expected to shrink. The ${}^6\text{He}$ ($2+$) state, which has widely spread two valence neutrons, becomes bound by a Λ , and the core E2 transitions ($5/2+$, $3/2+$ \rightarrow $1/2+$) are observed with rates (1/466 ps) and (1/1133 ps) and are competing against weak decay
- We propose to employ the “tagged-weak π -method” at H π S to measure B(E2)’s for $5/2+$ \rightarrow $1/2+$ and $3/2+$ \rightarrow $1/2+$ transitions of ${}^7_{\Lambda}\text{He}$
- Experimental determination of the level energies and the B(E2) will provide valuable information on the structure of ${}^6\text{He}$ and the effect of a Λ on the valence neutrons in it
- The weak decays from the $5/2+$, $3/2+$, and $1/2+$ states can explain the observed large spread of binding energy values of ${}^7_{\Lambda}\text{He}$, measured in emulsion, which was interpreted by Pniewski and Danysz as a weak decay from a long-lived hypernuclear isomeric states

${}^7_{\Lambda}\text{He}$ with $\text{H}\pi\text{S}$

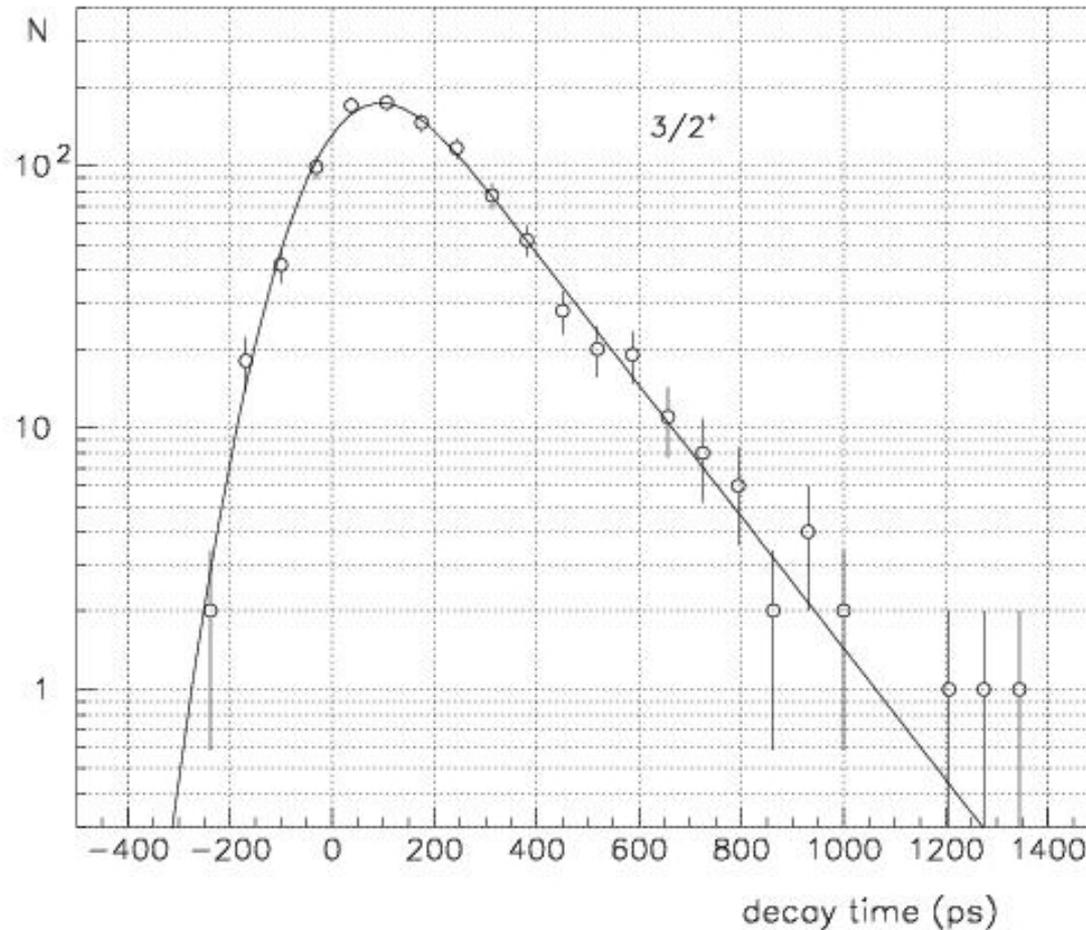

Simulated spectrum of the decayed pions from ${}^7_{\Lambda}\text{He} \rightarrow {}^7\text{Li} + \pi^-$ decay (96.8% - quasi-free, 2% - 115.06, 117.63 and 118.15 MeV/c monochromatic lines each with 0.66% probability). The monochromatic lines corresponds binding energies (states): 5.44 (1/2+), 3.75 (3/2+), and 3.4 (5/2+) MeV, respectively.

${}^7_{\Lambda}\text{He}$ with $\text{H}\pi\text{S}$

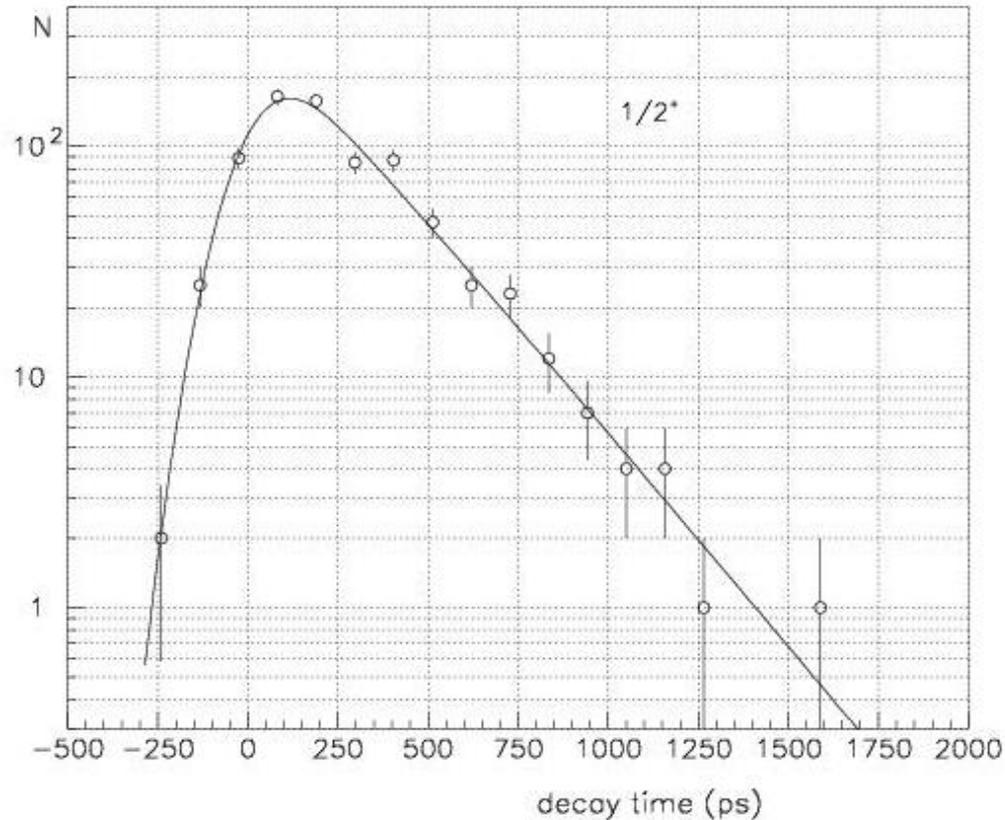

Simulated and fitted time spectrum of ${}^7_{\Lambda}\text{He} \rightarrow {}^7\text{Li} + \pi^-$ - weak-decay pions from the $5/2^+$ state. The input lifetime is 140 ps, the time resolution is 100 ps and the total number of events is 1000. The extracted lifetime is 139.6 ± 5.9 ps.

${}^7_{\Lambda}\text{He}$ with $\text{H}\pi\text{S}$

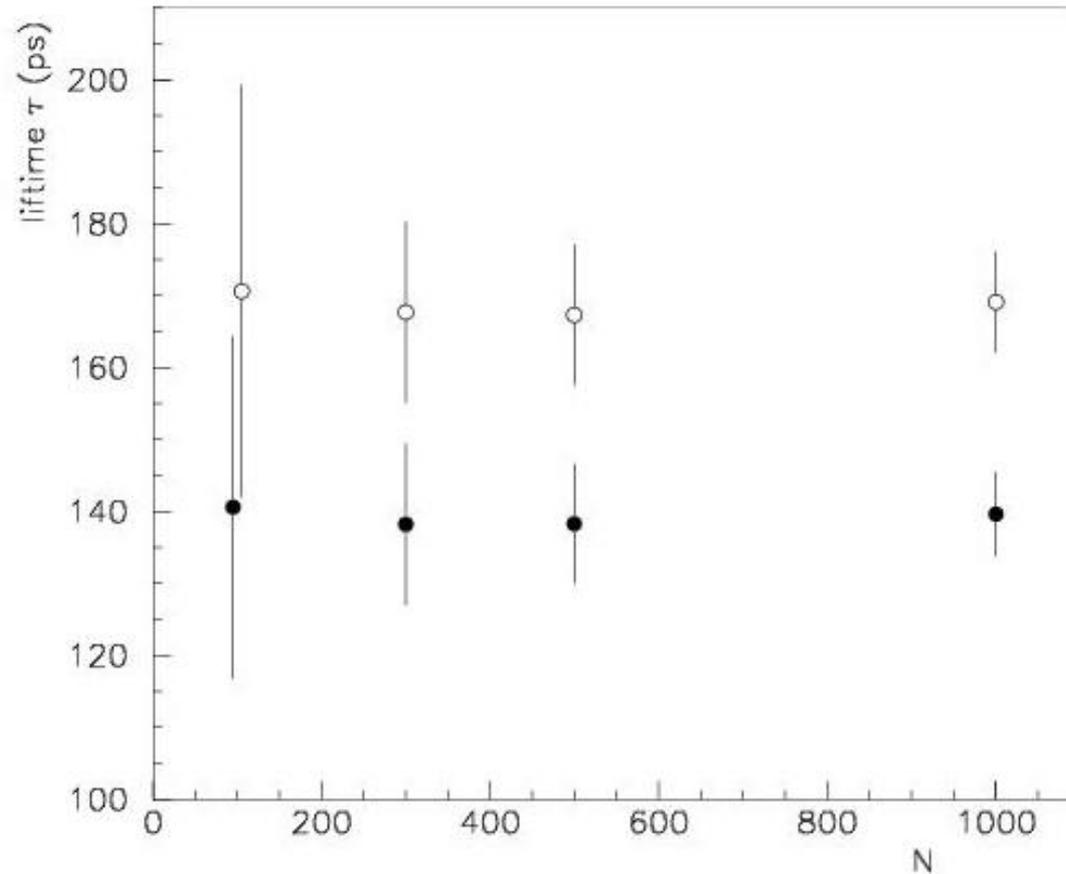

Simulated and fitted time spectrum of ${}^7_{\Lambda}\text{He} \rightarrow {}^7\text{Li} + \pi^-$ - weak-decay pions from the $3/2^+$ state. The input lifetime is 170 ps, the time resolution is 100 ps and the total number of events is 1000. The extracted lifetime is 169.1 ± 7.0 ps.

${}^7_{\Lambda}\text{He}$ with $\text{H}\pi\text{S}$

Simulated and fitted time spectrum of ${}^7_{\Lambda}\text{He} \rightarrow {}^7\text{Li} + \pi^-$ - weak-decay pions from the $1/2^+$ state by using the growth-decay function. The input lifetime is 200 ps, the time resolution is 100 ps and the number of events of the $5/2^+$, $3/2^+$ and $1/2^+$ states are 350, 425 and 725, respectively. The extracted lifetime is 204.5 ± 24.1 ps.

${}^7_1\text{He}$ with $\text{H}\pi\text{S}$

Sensitivity of lifetime measurement for $5/2+$ and $3/2+$ states. Lifetime error against number of events N .

Summary

- Tagged-Weak π -Method at H π S is a proper tool to measure $B(E2)$, $B(M1)$ for hypernuclear states with electromagnetic transition rates laying in the range (1/100ps)-(1/1000 ps)
- H π S with TOF based on RF phototubes will allow to investigate hypernuclear states with electromagnetic transition rates up to (1/20 ps)
